DESCRIPTION

PYRROLO[3,2-C]PYRIDINE DERIVATIVES AS TLR INHIBITORS

Technical Field

[0001]

The present invention relates to a heterocyclic compound having a Toll-like receptors (TLR)7, TLR9, TLR7/8, TLR7/9 or TLR7/8/9 inhibitory action, which is useful as an agent for the prophylaxis or treatment of TLR7, TLR9, TLR7/8, TLR7/9 or TLR7/8/9 related diseases such as autoimmune diseases, inflammatory diseases and the like, in particular, systemic lupus erythematosus, Sjogren's syndrome, rheumatoid arthritis, psoriasis, inflammatory bowel disease and the like.

Background of the Invention

[0002]

Toll-Like Receptors (TLRs) are conserved membrane pattern recognition receptors (PRRs) of innate immunity responsible for clearing microbial pathogens. TLRs are expressed in many immune and non-immune cells and detect pattern recognition motifs that recognize microbial products, namely, the pathogen associated molecular patterns (PAMPs, ex: nucleic acids, lipoprotein and polysaccharides) (Kawai et. al., 2011, Immunity, 34(5):637-50). In addition to PAMPs, several TLRs also recognize endogenous ligands resulting from cellular insult due to inflammatory response and cell-death, called damage associated molecular patterns (DAMPs) (Abdelsadik et. al, 2011, Human Immunology, 72, 1188-1193). Till date, ten functional TLRs (TLR1-10) have been identified in human, of which TLR1, TLR2, TLR4, TLR5 and TLR6, that recognize lipoproteins and lipopolysaccharides are expressed on the plasma membrane and TLR3, TLR7, TLR8 and TLR9 that recognize nucleic acids are expressed in endosomal compartments. While TLR7 and TLR8 both recognize ssRNA, TLR9 recognizes CpG-rich hypomethylated DNA (Table 1).

[0004]

Engagement of a cognate ligand to TLRs induces conformational changes allowing formation of homo- or heteromeric interactions within TLRs and recruitment of adaptor proteins such as MyD88, TIRAP, TRIF, and TRAM. TLR7 and TLR9 are localized mainly to ER in the steady state but traffic to the endo/lysosomal compartment with the help of UNC93b1 during activation (Kawai T and Akira S, 2007, Sem Immunol, 19, 24). TLR7 and TLR9 activate NF-κB and IRF7 via MyD88 to induce pro-inflammatory cytokines (TNFα, IL-1β, IL-6) and type I interferons (IFNα and IFNβ) respectively. The activation of NF-κB during TLR7 and TLR9 signaling is initiated from the endosomes whereas IRF7 activation is initiated from the lysosome-related organelle (LRO) after TLR7 and TLR9 are transported from the endosome to this vesicle. MyD88-dependent IRF7 activation in pDCs is mediated by activation of IRAK1, TRAF6, TRAF3 and IKKα. In conventional DCs and macrophages, TLR7 and TLR9 induce inflammatory responses by activating NF-κB via MyD88 but fail to activate IRF7 [Kawai et. al., 2011, Immunity, 34(5):637-50].

[0005] TLR7/9 activation plays a major role in the inter-phase
of innate and adaptive immunity. They not only activate inflammatory cytokines, up-regulate MHC molecules and co-stimulatory signals in antigen-presentation (innate immune response) but also prime and amplify T-, and B-cell effectors function (adaptive immune response) [Hannessy et. al., 2010, Nat Rev Drug Discov., 9(4):293-307; Koegh et. al., 2011, Trends Pharmacol Sci, 32(7):435-42].

[0006]

There is increasing evidence of role of TLR-7 and 9 in the pathogenesis of various autoimmune diseases including rheumatoid arthritis (RA). Human synovial tissue from RA patients showed the expression of TLR7 and 9 (along with TLR-2/3/4). The expression of TLR7 was significantly up-regulated in RA synovial fibroblasts (RASFs) compared with healthy controls or patients with non-inflammatory arthritis. Stimulation of cultured RASFs with TLR7 ligands resulted in significant up-regulation of chemokines, cytokines, metalloproteinases and type I IFNs. [Roelofs et. al., 2005, Arthritis Rheum. 52(8):2313-22].

[0007]

Recent studies have shown that the development and progression of Systemic Lupus Erythematosus (SLE) are driven by the over-expression of TLR-7, 8 and 9 within B-cells and pDCs [Komatsuda et. al., 2008, Clin Exp Immunol.;152 (3):482-7; Migita et. al., 2007, J Rheumatol., 34 (3): 493-500]. A knockout of TLR7 in a spontaneous murine model of SLE (MRL-/Mplpr/lpr), showed decreased anti-RNA antibodies, diminished spleenic immune activation and suppressed the development of nephritis [Nickerson et. al., 2010, J Immunol., 15, 184 (4):1840-8; Christensen et. al., 2006, Immunity, 25 (3): 417-28], validating the target in the pathogenesis of this disease. [0008]

Antagonists of these nucleic acid-recognizing TLRs have primarily been oligonucleotide-based molecules. IMO-3100, an oligonucleotide based antagonist of TLR7 and TLR9 has
demonstrated clinical activity in psoriasis patients. This antagonist has also shown encouraging results in mouse models of lupus, collagen induced arthritis and psoriasis. IMO-8400, a TLR-7/8/9 antagonist has been shown to suppress the production of autoimmune antibodies, improve kidney histopathology and decrease blood urea nitrogen and proteinuria in lupus prone mice.

[0009]

The small molecule anti-malarial drugs like chloroquine, hydroxychloroquine and quinacrine, that are also known to show TLR-7/8/9 antagonism, have been used since the 1950s to treat immune-mediated inflammatory disorders (IMID) such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). However, side effects associated with these drugs and also the suboptimal efficacy has limited the use of these anti-malarials in IMID.

[0010]

There is literature prior art disclosing small molecule TLR-7/8/9, TLR-7/9 and TLR9 antagonists. Coley Pharmaceuticals has disclosed series of 4-aminoquinoline derivatives as inhibitors of immune stimulation involving at least one of TLR9, TLR8, TLR7 and TLR3 (US 7410975). Eisai R & D has disclosed benzoxazole compounds as antimalarials, claiming the compounds being antagonists of TLR9 (WO 2010/036908). In a patent application (WO 2011/115183), Dainippon Pharma has disclosed monocyclic pyrimidine derivatives that are effective in the prophylaxis and/or treatment of disorders associated with signal transmission mediated by Toll-like receptors (TLR). The biological data disclosed in the application substantiate the claimed compounds as TLR9 antagonists. In a very recent patent application by Janus Biotherapeutics (WO 2013/052550), imidazoloquinolone-based compounds have been described as immune system modulators. Two more patent applications from Janus Biotherapeutics (WO 2012/167046 and WO 2012/167053) have described pyrazinopyrimidines and imidazolopyrimidines as
immune system modulators. In all the three patent applications, biological data reveal that the claimed compounds demonstrate TLR9 antagonism.

[0011]

Despite several discoveries in this area, there are no safe and efficacious orally administered small molecule TLR-7/8/9 antagonists available in the market. CPG-52364 from Coley Pharma and Pfizer has been discontinued from clinical trials in 2008 for unknown reason. Therefore, there is a strong need for a novel small molecule TLR-7/8/9 antagonist that will be orally available and will have potential clinical utility. These compounds will have medical application in the disease area of inflammation, autoimmune disorder and cell proliferation, rheumatoid arthritis, psoriasis, psoriatic arthritis, systemic lupus erythematosus, Sjögren’s Syndrome, multiple sclerosis, inflammatory bowel disease, allergic diseases, infectious diseases affecting immune system, asthma, type 1 diabetes, myasthenia gravis, hematopoetic disfunction, B-cell malignancies, transplant rejection and graft-versus-host disease.

When compound (I) is present as a configurational isomer, a diastereomer, a conformer and the like, each can be isolated by a known means. When compound (I) has an optical isomer, racemates can be resolved by a general optical resolution means, whereby an optically active forms ((+) form, (−) form) can be obtained.
When compound (I) has an optical isomer, a stereoisomer, a positional isomer, a rotamer or a tautomer, these are also encompassed in compound (I), and can be obtained as a single product according to synthesis and separation methods known per se.

For example, the method of optical resolution may be a method known per se, such as a fractional recrystallization method, a chiral column method, a diastereomer method etc.

1) Fractional recrystallization method

A method wherein a salt of a racemate with an optically active compound (e.g., (+)-mandelic acid, (-)-mandelic acid, (+)-tartaric acid, (-)-tartaric acid, (+)-l-phenethylamine, (-)-l-phenethylamine, cinchonine, (-)-cinchonidine, brucine etc.) is formed, which is separated by a fractional recrystallization method, and if desired, a neutralization step to give a free optical isomer.

2) Chiral column method

A method wherein a racemate or a salt thereof is applied to a column (a chiral column) for separation of an optical isomer to allow separation. In the case of a liquid chromatography, for example, a mixture of the optical isomers is applied to a chiral column such as ENANTIO-OVM (manufactured by Tosoh Corporation), CHIRAL series (manufactured by Daicel Chemical Industries, Ltd.) and the like, and developed with water, various buffers (e.g., phosphate buffer, etc.) and organic solvents (e.g., ethanol, methanol, isopropanol, acetonitrile, trifluoroacetic acid, diethylamine, etc.) as an eluent, solely or in admixture to separate the optical isomer. In the case of a gas chromatography, for example, a chiral column such as CP-Chirasil-DeX CB (manufactured by GL Sciences Inc.) and the like is used to allow separation.

3) Diastereomer method

A method wherein a racemic mixture is prepared into a diastereomeric mixture by chemical reaction with an optically
active reagent, which is made into a single substance by a
typical separation means (e.g., a fractional recrystallization
method, a chromatography method etc.) and the like, and is
subjected to a chemical treatment such as hydrolysis and the
like to separate an optically active reagent moiety, whereby
an optical isomer is obtained. For example, when compound (I)
contains hydroxy group, or primary or secondary amino group
within a molecule, the compound and an optically active
organic acid (e.g., MTPA [α-methoxy-α-
(trifluoromethyl)phenylacetic acid],
(−)-menthoxycetic acid etc.) and the like are subjected to
condensation reaction to give diastereomers of the ester
compound or the amide compound, respectively. When compound (I)
has a carboxyl group, the compound and an optically active
amine or an optically active alcohol reagent are subjected to
condensation reaction to give diastereomers of the amide
compound or the ester compound, respectively. The separated
diastereomer is converted to an optical isomer of the original
compound by acid hydrolysis or base hydrolysis.

The dosage form of concomitant drugs is not particularly limited, and is acceptable as long as the compound of the present invention is combined with concomitant drugs at the time of administration. Examples of such dosage forms are as follows:

(1) Administration of a single formula obtained simultaneous formulation of the compound of the present invention with a concomitant drug,

(2) Simultaneous administration via the same administration route for two kinds of formulas obtained by independent formulations of the compound of the present invention and a concomitant drug,

(3) Administrations at different times via the same administration route for two kinds of formulas obtained by independent formulations of the compound of the present invention and a concomitant drug,

(4) Simultaneous administration via different administration routes for two kinds of formulas obtained by independent
formulations of the compound of the present invention and a concomitant drug,

(5) Administrations at different times via different administration routes for two kinds of formulas obtained by independent formulations of the compound of the present invention and a concomitant drug (e.g., administration in the order of the compound of the present invention and then a concomitant drug, or administration in the reversed order).

These forms of administration are summarized below and abbreviated as a combination drug of the present invention.

[0196]

When administering the combination drug of the present invention, the concomitant drug and the compound of the present invention can be administered simultaneously.

Alternatively, the compound of the present invention can be administered after a concomitant drug is administered, or a concomitant drug can be administered after the compound of the present invention is administered. When administering at different times, the time difference depends upon the active ingredients to be administered, drug forms and methods of administration.

For example, when the concomitant drug or a pharmaceutical composition thereof is administered first, the compound of the present invention or a pharmaceutical composition thereof can be administered within 1 min. to 3 days, preferably within 10 min to 1 day and more preferably within 15 min to 1 hour after the concomitant drug or a pharmaceutical composition thereof is administered. When the compound of the present invention or a pharmaceutical composition thereof is administered first, the concomitant drug or a pharmaceutical composition thereof can be administered within 1 min to 1 day, preferably within 10 min to 6 hours and more preferably within 15 min to 1 hour after the compound of the present invention or a pharmaceutical composition thereof is administered.
If there are no problems with side effects of the concomitant drugs, any dosages can be set. A dosage as a concomitant drug varies depending on dosages, administration subjects, administration routes, target diseases, symptoms, etc. For example, in the case of oral administration in patients with systemic lupus erythematosus (adults, body weight of approximately 60 kg), a dosage range is generally about 0.1 to 20 mg/kg body weight, preferably from about 0.2 to 10 mg/kg body weight and more preferably from about 0.5 to 10 mg/kg body weight. It is preferable that this dosage is administered once daily to several times daily (e.g., once to 3 times).

If the compound of the present invention is used in combination with a concomitant drug, the respective dosages can be reduced within a safe range with consideration of the opposite effects of the respective drugs.

The combination drug of the present invention exhibits low toxicity. For example, the compound of the present invention or (and) the concomitant drug can be combined with a pharmaceutically acceptable carrier according to the known method to prepare a pharmaceutical composition such as tablets (including sugar-coated tablets and film-coated tablets), powder agents, granular agents, capsules (including soft capsules), liquids, injection solutions, suppositories, sustained-release agents, etc. These compositions can be administered safely orally or non-orally (e.g., including local, rectal, venous routes etc.).

The pharmaceutically acceptable carriers that can be used for manufacturing the combination drug of the present invention can be the same as those used in the medicament of the present invention as mentioned above.
A mixing ratio between the compound of the present invention and the concomitant drug in the combination drug of the present invention can be selected appropriately based on the administration subjects, administration routes, diseases and the like.

The concomitant drug in the combination drug of the present invention can be combined at an appropriate proportion if two or more drugs are combined.

A dosage of the concomitant drug can be selected appropriately based on the dosages used clinically. In addition, a mixing ratio between the compound of the present invention and the concomitant drug can be selected appropriately based on the administration subjects, administration routes, target diseases, symptoms, combinations, etc. For example, if the administration subject is humans, a concomitant drug may be used in an amount ranging from about 0.01 to 100 parts by weight relative to 1 part by weight of the compound of the present invention.

For example, the content of the compound of the present invention in the combination drug of the present invention varies with the form of formulations. Generally, it is present in a range from about 0.01 to 99.9 wt%, preferably from about 0.1 to about 50 wt% and more preferably from about 0.5 to about 20 wt% relative to the entire formula.

The content of the concomitant drug in the combination drug of the present invention varies with the form of formulations. Generally it is present in a range from about 0.01 to 99.9 wt%, preferably from about 0.1 to about 50 wt% and more preferably from about 0.5 to about 20 wt% relative to the entire formula.

The content of an additive such as carriers in the combination drug of the present invention varies with the form
of formulations. Generally it is present in a range from about 1 to 99.99 wt% and preferably from about 10 to about 90 wt% relative to the entire formula.

[0204]

5 When the compound of the present invention and a concomitant drug are formulated independently, the same contents can be applied.

[0205]

Since the dosages may fluctuate under various conditions as mentioned above, a dosage less than the dosages may be sufficient or it may be necessary to administer at a dosage exceeding the range.

Example

1H NMR (proton nuclear magnetic resonance spectrum) was measured by Fourier-transform type NMR. Peaks with very mild protons such as a hydroxyl group, an amino group and the like are not described.

In the following Reference Examples and Examples, mass spectrum (MS), nuclear magnetic resonance spectrum (NMR) and melting point were measured by the following apparatus.
MS (mass spectrum) was measured by LC/MS (liquid chromatograph mass spectrometer). As the ionization method, API (Atmospheric Pressure Ionization, atmospheric pressure chemical ionization) method or ESI (Electron Spray Ionization) method was used. The data indicate measured value (found) found. Generally, a molecular ion peak is observed. In the case of a compound having an amino group (-NH₂), a peak after elimination of NH₃ may be observed as a fragment ion. In the case of a salt, a molecular ion peak or fragment ion peak of free form is generally observed.

methanol (100 mL) was added a freshly prepared NaOMe methanol solution [prepared by dissolving sodium (2 g, 88.25 mmol) in methanol (100 mL)] at -20°C over 30 minutes. The resulting reaction mixture was stirred at 0–5°C for 16 hours. The resulting pale yellow solid was removed by filtration from the reaction mixture. The filtrate was poured into ice-water (500 mL) containing saturated NH₄Cl (150 mL). The resulting solid was collected by filtration, and dried under vacuum to give the desired product 2-2 as a pale brown solid (3.9 g, 46%).

Intermediate 2-I  ➔  Example A47

[0400]

A mixture of Intermediate 2-I (0.10 g, 0.398 mmol) and crude Intermediate 1-XIX (0.5 g, excess) in DMF (1.5 mL) was degassed in a stream of argon for 15 minutes. To this mixture was added 1,1-bis(diphenylphosphino)ferrocene-palladium(II) dichloride dichloromethane complex (0.028 g, 0.0398 mmol), and the reaction mixture was again degassed for additional 15 minutes. After stirring at 80°C for 18 hours, the volatiles were removed by evaporation, and the obtained residue was diluted with water (20 mL), followed by extraction with ethyl acetate (20 mL x 3). The combined organic layers were washed with brine (20 mL), dried over anhydrous Na₂SO₄, and concentrated under reduced pressure. The obtained residue was purified by silica gel column chromatography using 1% MeOH in dichloromethane as eluent to give the desired product **Example A47** (0.042 g, 20%) as a brown solid; LCMS: m/z 485.1 [M⁺+1].

[0403]

To a stirred solution of Example A20 (0.64 g, 1.30 mmol) in dichloromethane (2 mL) was added 2 M HCl in diethyl ether (2 mL). The reaction mixture was stirred for 2 hours at room temperature. After completion of reaction (monitored by TLC), the reaction mixture was concentrated under reduced pressure to obtain a residue, which was neutralized with saturated aqueous sodium bicarbonate solution (25 mL). The resulting reaction mixture was concentrated under reduced pressure to obtain a white solid, which was dissolved in 5% MeOH in dichloromethane, and the solution was filtered through a celite pad. The obtained filtrate was concentrated under reduced pressure to give the desired product Example A48 (0.42 g, 82 %) as a brown solid; LCMS: m/z 392.10 [M+1].

**Example B6**

**[0486]**

A mixture of Intermediate 3-IV (0.200 g, 0.68 mmol), Intermediate 1-II (0.337 g, 1.02 mmol) and K₂CO₃ (0.282 g, 2.04 mmol) in 4:1 mixture of dioxane/water (5 mL) was degassed in a stream of argon for 30 minutes. To the mixture was added PdCl₂(dppf) DCM (0.008 g, 0.010 mmol), and the reaction mixture was again degassed for additional 30 minutes. After stirring at 90°C for 18 hours, the reaction mixture was diluted with water (10 mL), followed by extraction with ethyl acetate (20 mL x 3). The combined organic layers were dried over anhydrous Na₂SO₄ and concentrated under reduced pressure. The obtained residue was purified by silica gel column chromatography using 5-10% MeOH in dichloromethane to give the desired product

Experimental Example 1

hTLR9 antagonism (SEAP inhibition assay) in HEK293 cell lines:

The SEAP reporter gene in HEK-Blue™-hTLR9 cells is placed under the control of the IFN-β minimal promoter fused to five NF-κB and AP-1 binding sites. The stimulation with a TLR9 ligand (ODN-2006) activates NF-κB and AP-1 which induces the production of SEAP. Levels of SEAP are determined with QUANTI-Blue™ detection medium that turns purple/blue in the presence of alkaline phosphatase. Decrease in the levels of SEAP production as indicated by reduction in absorbance at 650nm is directly co-related with the TLR9 inhibitory activity of the antagonist (NCE).

HEK-Blue™-hTLR9 cells were maintained in DMEM with 10% FBS, 1% Penicillin/Streptomycin/Amphotericin (complete growth medium) and 0.2% Normocin. For the assay, cells were dissociated by washing in 1X PBS and re-suspended in complete DMEM. Cells were seeded at a density of 20000 cells per well; (40μl per well) in a 384 well assay plate. 5μl of 10X antagonist (NCE) was added to the cells in triplicates for each concentration. The plate was incubated for half an hour at 37°C with 5% CO₂. 5μl of agonist (ODN-2006) was added and the plate was incubated overnight for 18 hours at 37°C with 5% CO₂. 5μl of supernatant was transferred to a 384 well reading plate and to this 45μl of Quanti-Blue™ detection reagent was added. The plate was then incubated for an hour at 37°C. SEAP activity in the supernatant was indicated by change in the pink color of Quanti-Blue™ detection reagent to purple/blue and the absorbance was read at 650 nm in the end point mode.

Experimental Example 2

mTLR9 and mTLR7 antagonism (cytokine release assay) in mouse splenocytes:
Materials:
Splenocytes isolated from male C57/BL6 mice
TLR7 ligand R0006 (IDT, 5’-rU*rU*rG*rU*rU*rG*rU*rU*rG*rU*rU*rU*rG*rU*rU*rU-3’), Liposomal transfection reagent - DOTAP (Roche, Cat.
No.11202375001), TLR9 ligand CpG ODN2006 (Sequence:
T*C*G*T*C*G*T*T*T*T*G*T*C*G*T*T*T*T*G*T*C*G*T*T;
* = phosphorothioate)
DMSO (Sigma, D2650), RPMI Powder (Sigma, R6504), Fetal Bovine
Serum (Gibco, 10270), Dulbecco’s Phosphate Buffered Saline
(Sigma, D1408), 96 well plate (Flat bottom, Costar 3599),
ELISA kit for IL-6 (EBioscience, 88-7064-77 and TNFa
(EBioscience, 88-7346-88), MACS Buffer (AutoMACS Rinsing
Solution (Miltenyl Biotec, 130-091-222) + 0.05% BSA), RBC
lysis buffer (0.85% NH4Cl), 40µm cell strainer (BD Falcon,
352340)
[0539]

Method:
A. Isolation of mouse splenocytes
Mouse spleen was isolated from C57BL6 mouse and stored in
1X chilled PBS buffer until further processed. Spleen was
transferred to a sterile petriplate and chopped in to 5-6
pieces in presence of MACS buffer (100µl) with the help of
fresh surgical blade and crushed with flat plunger of a
sterile syringe. A uniform suspension was prepared by passing
cells through a 40 µm cell strainer. Cells were centrifuged at
450xg for 5 minutes at 4°C, supernatant was discarded and
pellet dislodged gently, resuspended in 2 ml of pre-warmed
(37°C) RBC lysis buffer at room temperature with continuous
gentle mixing with 1 ml pipette. Lysis buffer was neutralized
with 12 ml of chilled MACS buffer and cells were passed
through 40 µm cell strainer. Cell suspension was collected in
15 ml MACS buffer and centrifuged at 450xg for 5 minutes at 4°C.
Pellet was resuspended in 15 ml MACS buffer and centrifuged at
400xg for 5 minutes. Cells were resuspended in 10 ml of RPMI
complete medium and viability was estimated by Trypan blue method.
Expected yield: 60-70 million cells from single mouse spleen.

mTLR9 antagonism (IL-6 and TNF-α release assay):
500 µM stock of CpG ODN-2006 was prepared in sterile, endotoxin-free water. Dilutions of 10x concentrations of NCEs were prepared in incomplete RPMI media, maintaining a final DMSO concentration of 0.3%. NCEs were added in a concentration range of 30 µM to 1 nM in respective wells of assay plate, assay medium containing 0.3% DMSO were added to control wells. 0.2 million splenocytes were added to all the wells and incubated at 37°C in 5% CO₂ incubator for 30 minutes. 1 µg/ml of respective agonist was added to all the wells except those were assigned as negative controls and mixed thoroughly.
Incomplete RPMI was added to negative control wells and incubated overnight at 37°C/5% CO₂. The plate was centrifuged at 450xg for 5 minutes at room temperature and the supernatant was collected. ELISA was performed as per manufacturer’s protocol. S/B Ratio, % Activity and % Inhibition was calculated using MS Excel. IC₅₀ and inhibition curve was generated using Graph Pad Prism.

mTLR7 antagonism (IL-6 and TNF-α release assay):
1 mg/ml stock of R0006 was prepared in sterile, endotoxin-free water. R0006 stock was diluted 10 fold with DOTAP and incubated for 30 minutes to form liposome complex (100 µg/ml of R0006). This complex was further diluted 10 fold with incomplete RPMI media (10 µg/ml of R0006) to achieve the final agonist concentration of 1 µg/ml. DOTAP alone was diluted 10 fold in incomplete RPMI media. NCEs were added in a concentration range of 30 µM to 1 nM in respective wells of assay plate, assay medium containing 0.3% DMSO were added to control wells. 0.2 million splenocytes were added to all the wells and incubated at 37°C in 5% CO₂ incubator for 30 minutes.
1 μg/ml of respective agonist was added to all the wells except those were assigned as negative controls and mixed thoroughly. DOTAP was added to negative control wells and incubated overnight at 37°C/5% CO₂. The plate was centrifuged at 450xg for 5 minutes at room temperature and the supernatant was collected. ELISA was performed as per manufacturer’s protocol. S/B Ratio, % Activity and % Inhibition was calculated using MS Excel. IC₅₀ and inhibition curve was generated using Graph Pad Prism.

hTLR9 % inhibition and mTLR7 and mTLR9, IL-6 and TNF-α release % inhibition at 1 μM concentration are given in Table 20 below.

**ND:** Not Determined

[0543]

Experimental Example 3

**Mouse Lupus Disease Model:**

Examples B6 and B11 were tested in well studied mouse model of lupus, lupus-prone MRL lpr/lpr mice that develop disease similar to human SLE [J Exp Med., 1978, 148 (5), 1198-1215]. These mice develop spontaneous systemic autoimmunity with both molecular (IFN signature) and clinical (autoantibody production and glomerulonephritis) features similar to human SLE. Anti-dsDNA antibodies are correlated with human SLE and the reduction in anti-dsDNA antibodies is believed to be of potential clinical benefit. Positive TLR7 and/or TLR9 target validation results have been reported for this disease model.

[0544]

**Mouse Lupus Disease Model Strain:**

Female MRL/lpr mice were purchased from Jackson Laboratories (USA) which manifest spontaneous lupus disease. Female MRL/lpr mice were treated for 9 weeks by oral route once a day with TLR-7/9 antagonists [Examples B6 and B11] at 3, 10 and 30 mg/kg doses. Prednisolone (2 mg/kg, P.O., QD) was used as a positive control during the studies. At the end of
treatment period, animals were sacrificed and blood samples were collected to estimate anti-dsDNA IgG titers using anti-dsDNA IgG ELISA kit, Alpha Diagnostics, USA.

Key findings for **Example B6** in the SLE disease model are as follows.

Mice treated with **Example B6** showed trend towards dose dependent reduction in mean anti-dsDNA IgG titers after 6 weeks of treatment at 3, 10 and 30 mg/kg doses (QD) [Fig. 1A].

Significant reduction in anti-dsDNA IgG was observed with 10 mg/kg once daily oral dose after 9 weeks of treatment [Fig. 1B].

Key findings for **Example B11** in the SLE disease model are as follows.

Mice treated with **Example B11** showed dose dependent reduction in mean anti-dsDNA IgG titers after 6 weeks of treatment at 3, 10 and 30 mg/kg doses (QD), significant at 30 mg/kg dose [QD] [Fig. 2A].

**Formulation Example 1**

(1) Compound of Example A1 10.0 g  
(2) Lactose 70.0 g  
(3) Cornstarch 50.0 g  
(4) Soluble starch 7.0 g  
(5) Magnesium stearate 3.0 g

After 10.0 g of the compound of Example A1 and 3.0 g of magnesium stearate are granulated in 70 ml aqueous solution of soluble starch (7.0 g as soluble starch) and then dried, and the resulting mixture is mixed with 70.0 g of lactose and 50.0 g of cornstarch (lactose, cornstarch, soluble starch and magnesium stearate are all products in compliance with Japanese Pharmacopoeia 14th Edition). The mixture is compressed to obtain a tablet.

**Industrial Applicability**

According to the present invention, the compound having a
